Discriminant Principal Components Analysis (DPCA)

(a) Scatter plot and PCA directions. (b) The same population but distinguishing patterns plus (+) and triangle (▼).

The problem of ranking components obtained by subspace learning techniques is addressed by the discriminant principal components analysis (DPCA) that aims to identify the most discriminant subspaces using weights given by separating hyperplanes [Thomaz and Giraldi, 2010].

Procedure for DPCA: for Two classes

1: Determine $P_{pca}$.
2: Form the matrix $\Theta$ given by $\Theta = (P_{pca})^T \tilde{\Theta}$, where $\tilde{\Theta}$ is the centered data matrix $\tilde{\Theta} = [\tilde{x}_1, \tilde{x}_2, \cdots, \tilde{x}_M]$;
3: Compute $\phi_{svm}$.
4: Sort the discriminant weights such that $|\phi_1| \geq |\phi_2| \geq \cdots \geq |\phi_{m'}|$.
5: Select the principal components according to the obtained $|\phi_i|$ sequence.
Ensemble: AdaBoost.M2

\[ h_f(x) = \text{arg max}_{y \in Y} \sum_{t=1}^{T} \alpha^t h^t(x, y) \]

SVM ensemble: \( y \in \{1, 2, \ldots, N\} \)

The Multi-Class.M2 DPCA pipeline consists of the following steps:

1. Apply PCA technique for dimensionality reduction in order to eliminate redundancy.

2. Compute a linear weak SVM ensemble $\phi_y^t$, based on the “one-against-all” SVM multi-class approach, where $y$ is a class.
   
   We build a weak SVM, which discards a percentage $\mu$ of the samples in the original data set to generate the training set [Garcia and Lozano, 2007].

---

Combine the discriminant weights computed through the separating weak SVM hyperplanes using AdaBoost.M2 as follows [Filisbino et al., 2015]¹⁴.

\[ |\Phi_{i,y}| = \left| \sum_{t=1}^{T} \alpha^t \phi_{i,y}^t \right|, \ y \in Y, \ i = 1, 2, \ldots, m' \]  

(1)

4 Compute \( v(i) = \max_{y \in Y} \{ |\Phi_{i,y}| \} \),

5 Sort discriminant weights: \( v(1) \geq v(2) \geq \ldots v(m') \)

6 Select the principal components according to the obtained \( v(i) \) sequence.

Radboud Database

Neutral Happy Sad Fear Angry

JAFFE Database
\[ d_i(x_r) = \sum_{j=1}^{k} \frac{1}{\lambda^j} (x_{rj} - \hat{x}_{ij})^2 \]
\[ l = \hat{x} + \delta \cdot q_i, \]  
\hspace{1cm} (2)  

where \( \hat{x} \) is the global mean, \( \delta \in \{ \pm j \cdot \bar{\lambda}^{0.5}, \quad j = 0, \pm 3 \} \), and \( \bar{\lambda} \) is the average eigenvalue of the total covariance matrix of PCA.

Visualization of the changes described by a principal direction, using the Radboud face database for three-class experiments, selected by:

(a)-(c) Multi-Class.M2 DPCA and (d)-(f) PCA
Computational Experiments

\[ RMSE^{l,i}(k) = \sqrt{\frac{\sum_{j=1}^{M} ||P_{I_k}^l P^T x_j - x_j||^2}{M}}, \]  

(3)

where the index \( l \) is a methodology, \( i \) is a class, \( I_k^l \) is a truncated identity matrix that keeps the selected subspace with dimension \( k \), \( P = P_{pca} \), and \( ||\cdot|| \) is the usual 2-norm.

5 classes (Radboud)

5 classes (Radboud)

(LNCC)
This paper proposes an extension of the DPCA technique for multi-class problems, named Multi-Class.M2 DPCA algorithm. In general, Multi-Class.M2 DPCA allow higher recognition rates using less linear features than standard PCA. Further work: use Bagging instead of AdaBoost.M2.
Multi-class discriminant analysis based on svm ensembles for ranking principal components.
